Abstract of the Disclosure

542210 298691

A method of forming a light emitting diode (LED) includes providing a temporary growth substrate that is selected for compatibility with fabricating LED layers having desired mechanical characteristics. example, lattice matching is an important consideration. LED layers are then grown on the temporary growth sub-High crystal quality is thereby achieved, whereafter the temporary growth substrate can be removed. A second substrate is bonded to the LED layers utilizing a wafer bonding technique. The second substrate is selected for optical properties, rather than mechanical proper-Preferably, the second substrate is optically transparent and electrically conductive and the wafer bonding technique is carried out to achieve a low resistance interface between the second substrate and the LED Wafer bonding can also be carried out to provide passivation or light-reflection or to define current flow.
